ACKNOWLEDGMENTS

I would like to thank my supervising professor, Dr. Raymond C. Loehr, for his hours of proofreading and guidance that made this report possible. His encouragement and suggestions made the process both enjoyable and at the same time a real learning experience for me. I would also like to thank Dr. Neal E. Armstrong for additional guidance and review as my second reader.

My gratitude also goes to Mr. Robert M. Organ of the Texas Water Commission, Information Resources Department, who was a great help in compiling the data and providing additional leads on the Texas semiconductor industry.

Dr. Donald V. Lassister, Consultant, (7127 Via Lomas, San Jose, CA 95139) provided invaluable advice and information on the California semiconductor industry that proved to be an integral part of the report. His assistance was very much appreciated.

I would like to thank the United States Navy for funding my graduate education. The self-discipline and dedication to duty I have learned in the Navy were invaluable the last 18 months.

Last, but definitely not least, I would like to thank my wife, Susan. As a "graduate school widow" for the last 18 months, she endured numerous late nights and lonely weekends for which I am eternally grateful.

CHAPTER 1 INTRODUCTION

The major objectives of this report are to: (a) provide the reader with the magnitude of the hazardous waste disposal problems facing the semiconductor manufacturing industry, and (b) explain how the minimization of hazardous waste can provide both economic benefits and reduced liability for this industry. Two important aspects of all waste minimization studies are the knowledge of quantity and characteristics of the waste streams in order to allocate scarce resources toward areas that provide maximum results. This report will provide this information related to the conditions of California and Texas based semiconductor manufacturers which provide almost forty percent of the semiconductor products in the United States. In addition, this report will review applicable environmental regulations which are important to future operations because they provide the impetus for waste minimization. Finally, successful case studies are summarized to give the reader an idea of which technologies are being used to minimize hazardous waste within the industry.

Semiconductors are electrical devices which perform a variety of functions including information processing and display, power handling, and the conversion between light energy and electrical energy. Production processes for semiconductors are complex involving over 100 proprietary solutions and 200 different generic materials to reach the final product. Detailed information on the manufacturing

process is provided in Chapter 2. Semiconductors are neither good insulators nor good conductors. They are semiconductors. Electrical current flow occurs through a solid media instead of a gas or vacuum as in several other types of electrical devices. Products of the semiconductor industry are used in computer microprocessor chips, communication equipment, electrical control devices, robotics, scientific test equipment, and numerous other electrical products.

The semiconductor manufacturing industry is expanding to meet the demands of a technically oriented society that must process information faster and more efficiently. Figures 1 and 2 show the current sales of semiconductor products and forecast a sizable expansion within the next two years.

Hazardous waste minimization within the industry is part of the national policy mandated by the United States Congress in the 1990 Pollution Prevention Act and the 1984 Hazardous and Solid Waste Amendments (HSWA) to the Resource Conservation and Recovery Act (RCRA). EPA elaborated on the concept in its 1986 Report to Congress (EPA 1986), stating that waste minimization is [25]:

"The reduction to the extent feasible, of hazardous waste that is generated or subsequently treated, stored or disposed of. It includes any source reduction or recycling activity undertaken by a generator that results in either (1) the reduction of total volume or quantity of hazardous waste, or (2) the reduction of toxicity of hazardous waste, or both, so long as such reduction is consistent with the goal of minimizing present and future threats to human health and the environment."

The semiconductor manufacturing process is part of a larger electronic products industry that generates significant quantities of spent solvent and aqueous metal containing hazardous wastes. Through the HSWA Amendments, land disposal of these wastes is prohibited unless the wastes are treated to Best Demonstrated Available Technology (BDAT), are delisted, or a "no migration petition" is obtained.

Minimizing these wastes at the source is driven by economic and liability incentives caused by increasing disposal costs and more stringent regulations. For example in 1987, the Hewlett Packard, San Jose, California semiconductor facility disposed of 38,000 gallons of solvent waste at an average cost of \$45 per gallon or \$1,710,000 total. The same amount of waste disposed of in 1980 would

have cost \$4 per gallon or \$152,000 total. The difference of \$1,558,000 was due to the fact that in 1980 land disposal of this waste was allowed, and in 1987 the majority of it had to be incinerated.

Typical hazardous waste streams generated by the semiconductor industry include waste rinsing water, spent process baths, waste acids and bases used for cleaning, and metal salts. More information on waste streams is provided in Chapter 4.

Hazardous waste minimization typically falls into one or more of five categories. These include process modification, material substitution, housekeeping, onsite reuse, and onsite recycling and reclamation [13]. Chapters 3, 6, and 7 expand on the advantages and disadvantages of waste minimization and how the semiconductor industry has implemented these categories to reduce hazardous wastes.

The disposal and liability problems of hazardous waste have affected all generators including the semiconductor industry. Highlighting this point, of the twenty eight EPA Superfund sites in the "silicon valley" area of California, twenty one (75%) are attributed to waste disposal practices related to the manufacture of semiconductor devices [15]. Federal laws dictate that generators could be held financially liable for all clean up costs associated with these sites. Facts like this are not uncommon in the United States and have prompted Congress and in turn the U.S. Environmental Protection Agency to require industries in

general to better manage their hazardous waste. Regulators and industry now recognize that waste reduction is the most economical and practical solution to the escalating hazardous waste crisis.

CHAPTER 2 THE MANUFACTURING PROCESS

The manufacturing process for semiconductor devices is a complex operation that involves numerous physical and chemical technologies and is the subject of many volumes of literature. A detailed explanation of the production process is not intended for the scope of this report. However, there are five major steps, each with its own waste streams, that are reviewed in this chapter so that the reader can better understand the generation of hazardous waste by the semiconductor industry. These five steps are oxidation, photolithography, etching, doping, and metallization.

The production of semiconductor devices starts with the introduction of elemental silicon, typically called the seed, into sealed quartz ampules at elevated temperatures and pressures. The ampules act as reaction chambers in which progressively more silicon is added to the initial seed until a cylindrical, crystal mass has formed inside the ampule to a specified diameter. This final form of the crystal is called an "ingot". Actually, other materials can be used to form the ingot, such as germanium, gallium arsenide, gallium phosphate, and gallium arsenic phosphide, but currently eighty percent of the ingots manufactured are seeded with silicon which is used for illustrative purposes in this discussion. The silicon ingots are then cut with sensitive diamond tipped saws into circular disks called "wafers". Wafers vary in diameter and thickness but approximately 28 wafers are cut from one inch of ingot length with diameters

between three and nine inches. This part of the process is called oxidation.

The wafers then undergo a series of photolithography, etching, doping, and metallization steps (see below) that actually add layers of electronic circuitry onto the wafer in square patterns. Between these square patterns on the wafer are "masked" areas to prevent buildup of circuitry and thus provide cutting areas to separate the squares. The wafer is then cut into these squares which are called "microchips", and depending on the application of the microchip and the size of the wafer, a hundred microchips could conceivably be produced from one wafer. This microchip is called a "semiconductor" and typically contains many layers of circuitry interconnected as specified for its particular application.

A significant feature in the production of semiconductor devices is the use of "clean" rooms that are engineered to prevent dust or other contaminants from landing on the wafers during this process and causing malfunctions in the electrical circuitry. These are required because the process engineers are trying to control physical and chemical processes on a molecular level to the point where some circuit lines are only micrometers (10^{-6} meters) thick. A speck of dust trapped in one of these layers of circuitry could ruin an entire chip.

The production process for semiconductors is diagramed in Figure 3. Typical waste streams are included for each of

Figure 3 Process Diagram for Semiconductor Manufacturing

the five major steps. It is important to note that this diagram does not include every step in the process but reflects the "over-all picture" for the readers knowledge.

Oxidation

Oxidation is the process of forming thin films of silicon dioxide one on top of each other to form a wafer. The process occurs in quartz ampule reaction chambers in the presence of oxygen or ultra pure water. Waste from this step include silicon dioxide or other raw material being used for wafer fabrication, hydrofluoric acid used to clean the quartz chambers, and waste rinsing water used to clean the wafers.

Photolithography

Photolithography is the procedure for forming extremely accurate patterns on the wafer. Prior to photolithography, the semiconductor wafer is coated with a thin layer of photoresist, containing an organic polymer, by spinning a small quantity on the wafer. A photoresist is a chemical that when applied to the wafer and exposed to an ultraviolet light pattern, displays that pattern without affecting the surrounding area of the wafer. A similar process is used in photography. The wafer is then heated to bond the polymer.

Ultraviolet light shining through a mask containing a circuit pattern determines where the polymer will be exposed. Some polymers are normally insoluble to a developer solution

but become soluble after exposure to ultraviolet light (positive resist), while others behave in a reverse manner (negative resist). The undeveloped photoresist is dissolved and removed using a "stripper" containing acids and caustics.

The photolithography process produces much of the wastes generated from the semiconductor manufacturing processes. Hexamethyldisilane (HMDS), which is typically used as an initial coating to increase the adhesion of photoresist, is a waste produced from the photolithography process. HMDS has a solvent base of xylene or Freon. Waste photoresist solvent and developers are also produced from the photolithography.

For negative photoresist processes, a waste mixture of isoprene rubber (the photoresist) and the developer (organic solvents including xylene and other nonhalogenated hydrocarbons) are produced. Positive photoresist produces a waste stream of orthodiazotketone (the photoresist) and the caustic (the developer).

Etching

Etching is used to dissolve away those places on the wafer which are not covered by the photoresist. This process exposes the silicon surface or substrate in preparation for doping with impurities. The etching process primarily uses acids to remove silicon dioxide and metals according to the patterns delineated by the photoresist.

Waste sulfuric, hydrofluoric, hydrochloric, phosphoric, nitric and chromic acids are produced as a result of etching

the semiconductor devices.

Doping

In doping (junction formation), diffusion or ion implantation techniques introduce impurities into select regions of the substrate (wafer) to form a boundary between conduction regions. In diffusion, the wafers typically are stacked in a long, heated quartz tube and exposed to gases containing impurities which diffuse into the exposed parts (i.e., areas not masked with photoresist) of the wafer. Ion implanters bombard the wafer with ionized impurities. Junction formation produces solid wastes containing arsenic, antimony, phosphorus, arsine, diborane and waste pump oils.

Metallization

Metallization is the process of depositing complex patterns of conductive material to interconnect the integrated circuits. Metallization wastes differ significantly depending on the specific plating process used. The waste streams from metallization include solutions of precious metals, heavy metals and acids.

Included at various stage of the process are rinsing steps utilizing electronic grade, distilled, deionized water (DDW) and generating dilute acid/water waste streams. These streams are the largest volume of non-hazardous waste generated in the manufacturing process. Typically these

steams are neutralized on-site and discharged into the local permitted Publicly Owned Treatment Works (POTW). Under the domestic sewer exclusion of RCRA [26], this waste steam is exempt from RCRA regulations (see Chapter 6) and is not regulated as a hazardous waste.

Table 1 shows that the volume of hazardous waste released by the U.S. Semiconductor Manufacturing Industry was approximately 7,775.1 tons in 1989 [30]. This information was obtained from Toxic Release Inventory Reports for Standard Industrial Classification (SIC) 3674 (Semiconductors and Related Devices). The requirement for these reports are explained in Chapter 5.

An attempt was made to obtain information on the amount of hazardous waste generated per some unit of production but was unsuccessful. This information is not available to the public, and the nature of this competitive industry is not to provide insight on their individual production processes.

CHAPTER 3 WASTE MINIMIZATION

Waste management generally refers to end-of-pipe systems for treating air emissions, wastewater, and hazardous waste. It is starkly different from waste minimization which utilizes technologies to reduce the source of wastes managed by end-of-pipe treatment processes. Waste minimization is the reduction or elimination of chemical emissions and hazardous waste generation by changes in product design and manufacturing technology. It involves both source reduction and recycling. Figure 4 shows the subcategories of each of these two activities. Waste minimization is an alternative to waste management for compliance with environmental laws. Waste minimization goes by other names including "pollution prevention" and "waste elimination". Waste minimization is driven by two ideas. First, waste management is an unproductive drain of company resources, and, second, companies that eliminate chemical emissions and solid and hazardous waste obtain a market advantage [18].

As environmental regulations become stricter, expenditures for waste management will increase. The costs of disposing of wastes by any means will become counter-productive, and because waste management requirements are driven by the regulations, companies will have little control over waste management costs. On the other hand, waste minimization avoids unproductive waste management costs. It conserves company funds for productive investment in new products and improved product quality.

Figure 4 Waste Minimization Techniques

SOURCE: EPA Waste Minimization Opportunity Assessment Manual (EPA/625/7-88/003)

DISINCENTIVES

There are disincentives to starting a waste minimization program. A significant obstacle to the implementation of waste reduction techniques is the technical barrier involving personnel attitudes and opinions relative to product quality. Semiconductor manufacturing, as an industry, is both highly competitive and economically conscious because of the market demand for a high quality, with reasonable cost, product. Source reduction activities involving in-process modifications or recycling could result in increases in the numbers of substandard product. Industry personnel are, therefore, highly sensitive to production changes. Extensive pilot testing and an active involvement by production division engineers and supervisors are key elements in changing opinions and attitudes regarding the use of a recycled chemical [1].

There could be possible disincentives to waste minimization in certain provisions the environmental statutes including RCRA. For example, recycle and reuse operations that are a major division of waste minimization could possibly trigger additional requirements changing the individuals permit status from a "Generator" of hazardous waste to a "Treatment Facility." The additional permit would not be required if the operation met one of the following three exemptions [23]: (1) the recycled material is directly used as ingredients or feedstocks in production process; (2) the recycled material is directly used as effective

substitutes for commercial chemical products; or (3) when the recycled material is returned as substitutes for raw material feedstock to the original primary production process in which they were generated (i.e., closed loop processes).

Basically, if a RCRA solid waste is being recycled for sale as a product, this operation would be considered a treatment process and have to be permitted as such.

In addition to the permitting restrictions associated with RCRA, several companies, with National Pollutant Discharge Elimination System (NPDES) permits, that have wanted to increase or modify their operation have been reluctant to do so [1]. Expansion or modification to their onsite operations could require revision to their existing NPDES permits to authorize a change in the composition and flow rate of their discharge. The process of revising a NPDES permit and the potential for more stringent discharge limitations has discouraged companies from modifying or expanding their operations.

INCENTIVES

As mentioned earlier, a increasing cost of pollution control is the indirect incentive for minimizing hazardous wastes. Equally important as the increasing costs are the health and financial risks associated with the transportation of the waste, the potential for mismanagement of the waste by the facility operators, and the possibility of improper design or operation of the disposal facility resulting in a

release of contaminated material in the environment. Any one of these scenarios would require the "responsible party" (RP) to remediate the release to a condition that protects human health and the environment. This requirement comes from Section 106 and 107 of the Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (CERCLA). The cost of such an action varies as to the severity of the release, but costs in the millions of dollars are not uncommon.

In response to the increasing costs and liability associated with offsite disposal, several companies have initiated programs aimed at the reduction of hazardous waste generation. These programs exist among the larger semiconductor firms which have the personnel and finances to support them. Table 2 shows the total chemical releases for twelve semiconductor manufacturing companies, and, as can be seen, there have been substantial reductions in chemical releases for most of them. According to Semiconductor International [24], "reductions were achieved in several ways including chemical substitution, waste minimization, recycling, and improved process and pollution controls." In actuality, the reductions could be due to many factors, including volume of business, but waste minimization controls surely are a contributing factor. Chapters 6 and 7 will detail some case studies that have proved successful in this regard.

In most of the case studies reviewed, the motivating

**Table 2 Semiconductor Company Chemical

Source: October 1991 Semiconductor International

forces were reduction in cost and reduction in the potential liability associated with offsite management activities. While strict quality control in production activities can cause resistance to process change and innovation, the potential for significant cost savings in a very competitive and cost-conscious industry can be used to enhance acceptance to waste minimization techniques.

CHAPTER 4 ENVIRONMENTAL REGULATIONS

Environmental regulations are the major impetus for minimizing hazardous wastes in the semiconductor industry. Pollutants tend to be disposed of in the "least regulated" part of the environment (air, water, or land), but recent legislation by the Federal Government and a few States have been aimed at "tightening" laws regulating the disposal of hazardous waste. Federal laws reviewed in this chapter are the: (a) Clean Air Act; (b) Clean Water Act; (c) Pollution Prevention Act, and (d) the Resource Conservation and Recovery Act with perspective on how they encourage waste minimization activities. Two State laws are also reviewed. These are California's Source Reduction and Hazardous Waste Management Review Act of 1989 and Texas' Senate Bill 1099 of 1991, which incorporated new provisions of the Texas Solid Waste Disposal Act. These two states are "breaking new ground" in the effort to encourage industries generating hazardous waste to thoroughly plan and implement waste minimization into their production operations.

Federal Regulations

Clean Air Act

As shown in Figure 6, Chapter 5, almost one-third of the wastes generated by the California semiconductor manufacturers from 1987 to 1990 were volatile organic compounds (VOCs) released directly into the atmosphere

without pretreatment. On November 15, 1990, major amendments to the Clean Air Act (CAAA) were adopted in an effort to change such disposal practices. After more than a decade of political stalemate, the Amendments were signed into law and will result in controls to be phased in over the next thirty years.

The major impacts of the CAAA are the ozone National Ambient Air Quality Standards (NAAQS) nonattainment regions and the Air Toxics Program that were instituted. The Air Toxics Program will affect semiconductor manufacturers that have previously seen little air quality regulations. The NAAQS provisions will require major reductions in future VOC emissions. Significant deadlines are given in Table 3 [27] that will affect the disposal of pollutants generated by the semiconductor industry.

The new Air Toxics Program was written to regulate sources of hazardous air pollutants instead of individual pollutants. For example, air toxic standards could be set for semiconductor manufacturing facilities which will be categorized as either a "major source" or as an "area source". The definition of a major source is any stationary source (i.e. building, structure, or facility) that emits more than 10 tons per year of any of the 189 listed hazardous air pollutants, or 25 tons per year of any combination of these pollutants. Semiconductor facilities do not typically generate these amounts of pollutants and will most likely be subcategorized as an area source which is any stationary

**Table 3 - Significant Deadlines Set by the
Clean Air Act Amendments of 1990**

Date	Action
11/15/91	EPA must promulgate regulations providing for the issuance of production allowances for class I and II ozone depleting substances.
11/15/91	EPA is required to promulgate regulations banning the production of nonessential products that release class I ozone-depleting substances into the environment.
2/15/92	EPA and the National Academy of Sciences (NAS) must submit to Congress a study of the roles of ozone precursors in tropospheric ozone production.
5/15/92	EPA must promulgate requirements for enhanced ozone monitoring programs to be implemented in serious, severe, and extreme ozone nonattainment areas.
11/15/92	EPA must promulgate standards applicable to emissions of VOCs and any other air pollutant from loading and unloading of tank vessels for all such operations that are determined to contribute to air pollution or that are anticipated to endanger public health or welfare.
11/15/92	EPA is required to study the potential hazards of hydrofluoric acid and its uses in industrial and commercial applications. A report to Congress must be submitted by this date.
11/15/92	The ban on nonessential products that release class I ozone depleting substances into the environment becomes effective.
11/15/93	EPA must issue VOC emission control technique guidelines for all RCRA permitted treatment, storage, and disposal facilities. Existing control technique guidelines must also be reviewed by this date.
11/15/93	EPA is required to identify alternative control technologies for all categories of stationary sources of VOCs that have the potential to emit 25 tons per year.
11/15/93	EPA must submit a report to Congress on VOC emissions from consumer and commercial products, determine their potential to contribute to ozone levels, and establish criteria for their regulation.
11/15/93	EPA must submit its first report to Congress on production, use, and consumption of ozone-depleting substances
11/15/95	EPA is required to list categories and subcategories of sources representing at least 90% of the emissions of the 30 hazardous air pollutants presenting the greatest threat to public health in the largest urban areas subject to regulations

SOURCE: The Hazardous Waste Consultant, Jan/Feb 1991

Table 3 - Continued

Date	Action
11/15/96	VOC emissions must be reduced by at least 15% from 1990 levels by November 15, 1996 in ozone nonattainment areas.
11/15/96	EPA must submit a report to Congress on residual risk from hazardous air pollutants, including recommendations for legislation to control such risk.
11/15/99	EPA must ensure that all sources are in compliance with the national urban air toxics strategy.
12/31/99	EPA must promulgate a production phase-out schedule for class II ozone-depleting chemicals.
1/1/00	The production and consumption of class I ozone-depleting chemicals, except methyl chloroform, is prohibited.
11/15/00	EPA is required to promulgate standards for all listed categories and subcategories of sources of hazardous air pollutants.
1/1/02	The production and consumption of methyl chloroform is prohibited.
1/1/15	Production limits on class II ozone-depleting chemicals begins.
1/1/30	The production of class II ozone depleting substances is prohibited.

source that is not a major source. The amendments require EPA to set standards for emission rates for all categories by November 15, 2000.

Waste minimization is directed through these standards by requiring a Maximum Achievable Control Technology (MCAT) designed to reduce emissions. Section 112(d)2 of the CAAA state, "emissions standards promulgated under this subsection and applicable to new or existing sources of hazardous air pollutants shall require the maximum degree of reduction in emissions of hazardous air pollutants subject to this section (including a prohibition on such emissions, where achievable)...through application of measures, processes,

methods, systems or techniques including, but not limited to measures which reduce the volume of, or eliminate emissions of, such pollutants through process changes, substitution of materials or other modification..." . As a minimum, the MCAT standards must be reviewed by EPA every eight years and revised as needed.

Clean Water Act

Figure 6, Chapter 5 shows that more than one-third of pollutants generated by the California semiconductor manufactures are discharged into the local Publicly Owned Treatment Works (POTW). As noted in Chapter 2, this waste stream is exempt from RCRA Subtitle C regulations, but is regulated by the Clean Water Act and the National Pollutant Discharge Elimination System (NPDES) program. Large quantities of dilute waste acid are generated in the manufacture of semiconductors which are typically neutralized (pretreatment) onsite and sent to the POTW which must be specifically permitted to receive such wastes.

In 1990, EPA issued revisions to the pretreatment rule that will mostly likely increase disposal costs and subject semiconductor manufacturers to more stringent requirements for this avenue of disposal. The underlying motive is again to encourage waste minimization at the source. The revisions are aimed at controlling hazardous waste discharges to POTWs. The regulations impose new discharge, reporting and permitting obligations on Significant Industrial Users (SIUs)

discharging to POTWs, including revisions to the prohibited discharge standards, permit requirements for additional classes of SIUs, and a new definition and restrictions of slug discharges.

The regulations also impose five additional obligations on most POTWs including: (a) a mandatory requirement that all SIUs be issued a permit or its equivalent by the POTW; (b) a requirement that the POTW conduct at least one inspection and sampling visit annually on all SIUs; (c) that POTWs develop an enforcement response plan; (d) conducting a written evaluation of the need to revise local limits when the SIUs NPDES permit is renewed; and (e) that most POTWs provide whole-effluent biological toxicity testing results with NPDES renewal applications.

Pollution Prevention Act of 1990

Signed into law on October 27, 1990, the Pollution Prevention Act declares that, whenever feasible, pollution prevention either in the form of source reduction, recycling, treatment or proper disposal, in this order, is a national policy of the United States. Though no statutory requirements are levied on industry mandating waste minimization, this Act revised the reporting requirements under the Toxics Release Inventory (TRI) provisions of SARA Section 313 to provide information on hazardous waste minimization activities with each annual filing.

Resource Conservation and Recovery Act (RCRA)

RCRA and the 1984 Hazardous and Solid Waste Amendments (HSWA) continues to be the central driving factor in hazardous waste minimization. Figure 6, Chapter 5 shows that thirty eight percent of the wastes generated by the California semiconductor manufacturers from 1987 to 1990 were disposed of offsite. HSWA land ban restrictions for the disposal of hazardous waste have all taken effect, so the majority of this waste is processed by incinerators, deep well disposal, or waste exchange programs. As described earlier in Chapter 3, this method of waste management can be both costly and risky.

The manifest system used to track and report on each hazardous waste shipment requires all generators to certify that the volume or toxicity of their waste is reduced to the maximum degree that is economically possible. Biennial reports must document efforts by the generator to reduce the waste volume, toxicity, and actual amount of reduction achieved.

State Regulations

California's Source Reduction and Hazardous Waste Management Review Act of 1989

The goals of this Act are threefold: (a) first to reduce hazardous waste generation; (b) second to reduce chemical releases into the environment; and (c) third to document

source reduction methods so that this information can be made available to other generators. This Act goes one step further than the Federal Regulations in that fines of \$1,000 per day can be levied against a generator that is not complying with the full intent of the law.

In summary, generators that produce more than 26,400 pounds of hazardous waste per year or more than 26.4 pounds of extremely hazardous waste per year must generate two public reports specifically documenting their efforts toward minimizing hazardous wastes. The first is the Source Reduction Evaluation Review Plan which documents the generators efforts to identify, evaluate, and select source reduction methods. This document must prove that an "honest" attempt at minimizing hazardous waste is being made. It involves six major steps which include: (a) determining if a plan must be prepared; (b) identifying major waste streams; (c) developing and screening source reduction alternatives; (d) performing a detailed evaluation of potentially viable alternatives; (e) selecting and implementing source reduction measures; (f) and certifying that the document is accurate and complete.

The second required document is the Hazardous Waste Management Performance Report which annually records the effectiveness of the generators waste minimization plan.

It is important to note that this law specifically requires generators of neutralized waste acid disposed of in POTWs, mentioned in Chapter 2 as a major waste stream of

semiconductor manufacturing process, to have a written plan for reducing the quantity of this waste stream.

Texas Senate Bill 1099

This Bill, effective January 3, 1992, incorporated new provisions into the Texas Solid Waste Disposal Act (TSWDA) concerning source reduction and reporting of hazardous waste minimization activities. In summary, this bill provides the framework to implement "the policy of the state to reduce pollution at its source and to minimize the impact of pollution in order to reduce the risk to public health and the environment and continue to enhance the quality of air, land, and waters of the state where feasible." It goes on to state, "hazardous wastes, pollutants, and contaminants that cannot be reduced at the source should be minimized where possible. Waste minimization, while secondary in preference to source reduction, is an important means for achieving more effective protection of public health and the environment."

This Bill affects both large quantity generators of hazardous waste, defined as generating more than 1,000 kilograms of hazardous waste or one kilogram of acute hazardous waste generated per month, and small quantity generators of hazardous waste, defined as generating between 100 and 1000 kilograms of hazardous waste per month or less than one kilogram of acute hazardous waste generated per month. The bill requires a five year "Source Reduction and Waste Minimization Plan" to be maintained by the generator on

site at all times for inspection by state regulators.

For a large quantity generator, the major parts of this plan include: (a) a survey of activities that release pollutants including quantities; (b) a prioritized list of economically and technologically feasible source reduction and waste minimization projects; (c) an explanation of source reduction or waste minimization projects to be undertaken; (d) an estimate of the type and amount of reduction anticipated; (e) a schedule of implementation of each project; (f) source reduction and waste minimization goals for the entire facility; (g) an employee training program to aid in accomplishing the goals; and (h) certification by the owner or officer of the facility who has authority to commit resources to the plan that it is correct and complete. For a small quantity generator, the requirements for the plan are not quite as detailed but include the same framework to ensure source reduction is given primary consideration.

The Bill requires an annual report by the generator to the Texas Water Commission or Texas Air Control Board updating the plan. The plan is not available for public viewing, but an executive summary signed by the owner or an officer of the firm must be on file at the appropriate state agency for public review.

CHAPTER 5 GENERATION AND DISPOSITION OF SEMICONDUCTOR WASTE

Two fairly extensive studies were sponsored in 1987 [1] and 1991 [9] by the Semiconductor Industry Association (SIA), Cupertino, California related to the generation and disposal of hazardous waste by United States semiconductor manufacturing facilities. The basis of each report was the compilation of data on the quantity and characteristics of waste generated during the semiconductor manufacturing process. The following discussion adds additional waste generation data on twenty-two Texas based semiconductor manufacturing facilities for 1988 and 1990. The development and compilation of the Texas data accomplishes the following objectives [1]:

1. Provide industry with practical information on current waste generation and disposal practices helping to develop responses to forthcoming regulations.
2. Provide regulators with an adequate information base to realistically determine what needs exist and what actions can be taken to encourage waste minimization.
3. Facilitate technology transfer within the industry by aiding in developing a waste audit for individual manufacturing facilities.

The information provided on the Texas based semiconductor manufactures was compiled by obtaining a complete solid waste record from the Resource Information Division, Texas Water Commission, Austin, Texas for Standard Industrial Classification (SIC) Code 3674, Semiconductors and

Related Devices. Table 4 is a summary from these records of the hazardous waste streams generated by eighteen companies operating 22 manufacturing facilities in Texas. Appendices A, B, and C are the supporting documents for Table 4.

Appendix A includes the types of hazardous waste generated by all Texas manufacturers that dispose of waste under SIC 3674. Appendix B gives the amounts of waste generated by eighteen of these companies in 1988, and Appendix C contains the same information for 1990.

The report sponsored by SIA in 1987 relied on a battery of survey forms sent to fifty United States semiconductor manufacturers on hazardous waste generation and minimization practices [1]. Sixteen responses were received which indicated that more than ninety eight percent of the waste produced by the facilities was composed of the following seven waste streams:

1. Dilute waste acid
2. Hydrogen fluoride waste acid
3. Non-halogenated solvents
4. Halogenated Solvents
5. Metal bearing liquid
6. Stripper
7. Positive and negative photoresist

The primary objectives of the 1987 report was to: (1) generate reliable information on the characteristics and quantity of liquid and solid waste being generated industry-wide; (2) identify and compare disposition practices from

commonly applied processes and operations of the semiconductor industry; and (3) document, and thus encourage, reductions in waste generation industry wide.

The report sponsored by SIA in 1991 [9] attempted to obtain waste data via survey forms from a broad base of U.S. semiconductor manufacturers but had minimal response due to lack of response [22]. It is currently in draft form and has not been finalized. However the report does provide extensive waste generation and disposal data for 85 California based semiconductor manufactures from 1987 through 1990. The data was obtained from public reports filed annually by semiconductor manufacturers as required by Section 313 of the Superfund Amendments and Reauthorization Act (SARA) [23]. Under this requirement, manufacturers are required to provide volume of waste generated and the avenue of release for this waste. The five avenues of release include: air, water, land, POTW, and off-site.

Table 5 provides the combined releases of thirty-six chemicals to the air, POTW, and off-site by the California semiconductor manufacturers for the years 1987 through 1990. The percentage of the total is also given for a sense of the relative volume of each waste type generated. Table 6 is a subset of Table 5 reduced to yearly totals for thirteen chemicals that comprise at least seventy percent of the waste stream for 1987, 1988, 1989, and 1990. These chemicals generally make-up the majority of waste generated by the California semiconductor industry.

Table 5 - Total Chemical Releases for 1987-1990
(California Semiconductor Industry)

Chemical Name	Total Releases (lbs)	Percent of Total
1,1,1 Trichloroethane	893,227	6.88
1,1,2 Trichloroethane	15,078	0.12

Tables 4, 5, and 6 provide an important component of successful waste minimization studies, namely, knowing the characteristics and mass of each waste stream is vitally important to focus effort on those areas of an industry that will provide the most reduction for the limited resources available. The information provided shows a trend of waste reduction from 1987 to 1989 that could be attributed to waste minimization. As stated earlier, the report is in draft form at this time and final conclusions in this regard were not available. The information is reported in "pounds" which is typically not a standard descriptive unit for liquid wastes, but SARA Section 313 requires that generators report the quantity of waste released in pounds. Reporting the units in terms of volume, gallons or liters, is possible but would require uniform densities for each chemical. The EPA form used by companies to report this information under SARA Section 313 is called "Form R". This form requires the generator to list waste volumes in pounds or tons depending on relative magnitude.

Figure 5 shows the relative volumes of waste released into each of these five avenues. As discussed in Chapters 2 and 4, a sizable portion of the waste generated by semiconductor manufacturing operations is a dilute acid steam that is released to the local POTW and is regulated under the manufacturing facilities NPDES permit. This waste accounted for more than one-third of the waste reported by California manufacturers. The remaining two-thirds were released to

1987 through 1990

either the atmosphere, via the "attainment" regulations of the Clean Air Act discussed in Chapter 4, or off-site to incinerators, blending operations, or deep well disposal. Figures 6, 7, and 8 show the major chemicals that are released into the air, POTW, and off-site respectively. An apparent inconsistency in these three figures are the number of chemicals included in the "other" category. The numbers vary because not each chemical is released to each avenue. For example, sulfuric acid which was released to the local POTWs or Air avenues was not released Off-site. As discussed in Chapter 4, the VOCs and CFCs shown in Figure 6 are typically released to the air without treatment and will face more stringent regulations in the near future.

The data presented on the Texas based Semiconductor industry obtained from the Texas Water Commission, Austin, Texas is consistent with the 1987 SIA report that listed the seven waste streams that comprised ninety eight percent of the generated waste. The information presented in the draft 1991 SIA report investigated a different perspective of the waste streams within the California industry. The 1991 report details which avenue the waste stream is disposed and attempts to break down the waste stream into individual chemicals.

As state earlier in the objectives of this chapter, the development of waste data for any waste minimization study, either on an industry wide scale or for an individual plant, is a critical first step. EPAs Waste Minimization

Opportunity Assessment Manual [14] states, "material balances are important for many WM (waste minimization) projects, since they allow for quantifying losses or emissions that were previously unaccounted for...and assist in developing the following information: (1) baseline for tracking progress of the WM efforts; (2) data to estimate the size and cost of additional equipment and other modifications; and (3) data to evaluate economic performance."

The data presented were purposefully separated into the largest waste streams with the smaller components lumped into the "other" category or else not provided. It is logical to conclude that money spent for waste minimization ought to target those waste streams that will provide the greatest economic benefits. This is not to say that certain technologies will not work well for smaller waste streams in terms of payback and liability reduction, but that the larger waste streams typically provide the greatest opportunity for reduction. An example of the latter is given in Case Study 2, Chapter 6, where Methyl Pyrrolidone was recycled at a particular manufacturing plant with a payback of 18 months. Table 4 lists Methyl Pyrrolidone as the eighteenth largest waste of the Texas based semiconductor manufacturers, but for one particular operation, its reduction provided maximum benefit.

One item that may not be evident in the acquisition of this data under SIC 3674, Semiconductor and Related Devices, is the amount of waste generated by "Related Devices". To

some extent, each report cited, including Texas waste, was generated from annual reports of manufacturers under this SIC. Looking closely at Appendix A, the "Related Devices" waste encompasses more than just semiconductors. The delineation of the two categories is not possible without looking at individual operations to see which waste is solely due to the manufacture of semiconductor devices. Because this discussion deals with "Waste Minimization in the Semiconductor Industry," the reader should take this into account. After looking at many different waste streams produced by the semiconductor industry, it is felt that the data presented is a fairly accurate representation of semiconductor generated waste.

CHAPTER 6 RECYCLING

Figure 4, Chapter 3, outlines recycling as one of the two main divisions of waste minimization techniques recognized by the EPA and includes both onsite and offsite operations. The following two recycling case studies have shown how hazardous waste generated in two semiconductor manufacturing operations can be successfully minimized, and, as seen in Figures 7 and 8, the technologies used are common to many different manufacturing processes.

A material is "recycled" if it is used, reused, or reclaimed (40 CFR 26.1 (c)(7)). A material is used if it is either (1) employed as an ingredient (including its use as an intermediate) to make a product or (2) employed in a particular function as an effective substitute for a commercial product (40 CFR 261.1 (c)(5)). A material is "reclaimed" if it is processed to recover a useful product or if it is regenerated.

Case Study 1

The first Case Study involved the application of a hydrofluoric acid (HF) chemical reprocessor developed by the Athens Corporation, Oceanside, California to recycle and repurify HF solutions [3]. The reprocessor has limited full scale manufacturing experience but is a promising product for waste minimization. The SEMATECH Consortium of Austin, Texas currently has one in operation under study.

Hydrofluoric Acid is used in the cleaning of the quartz

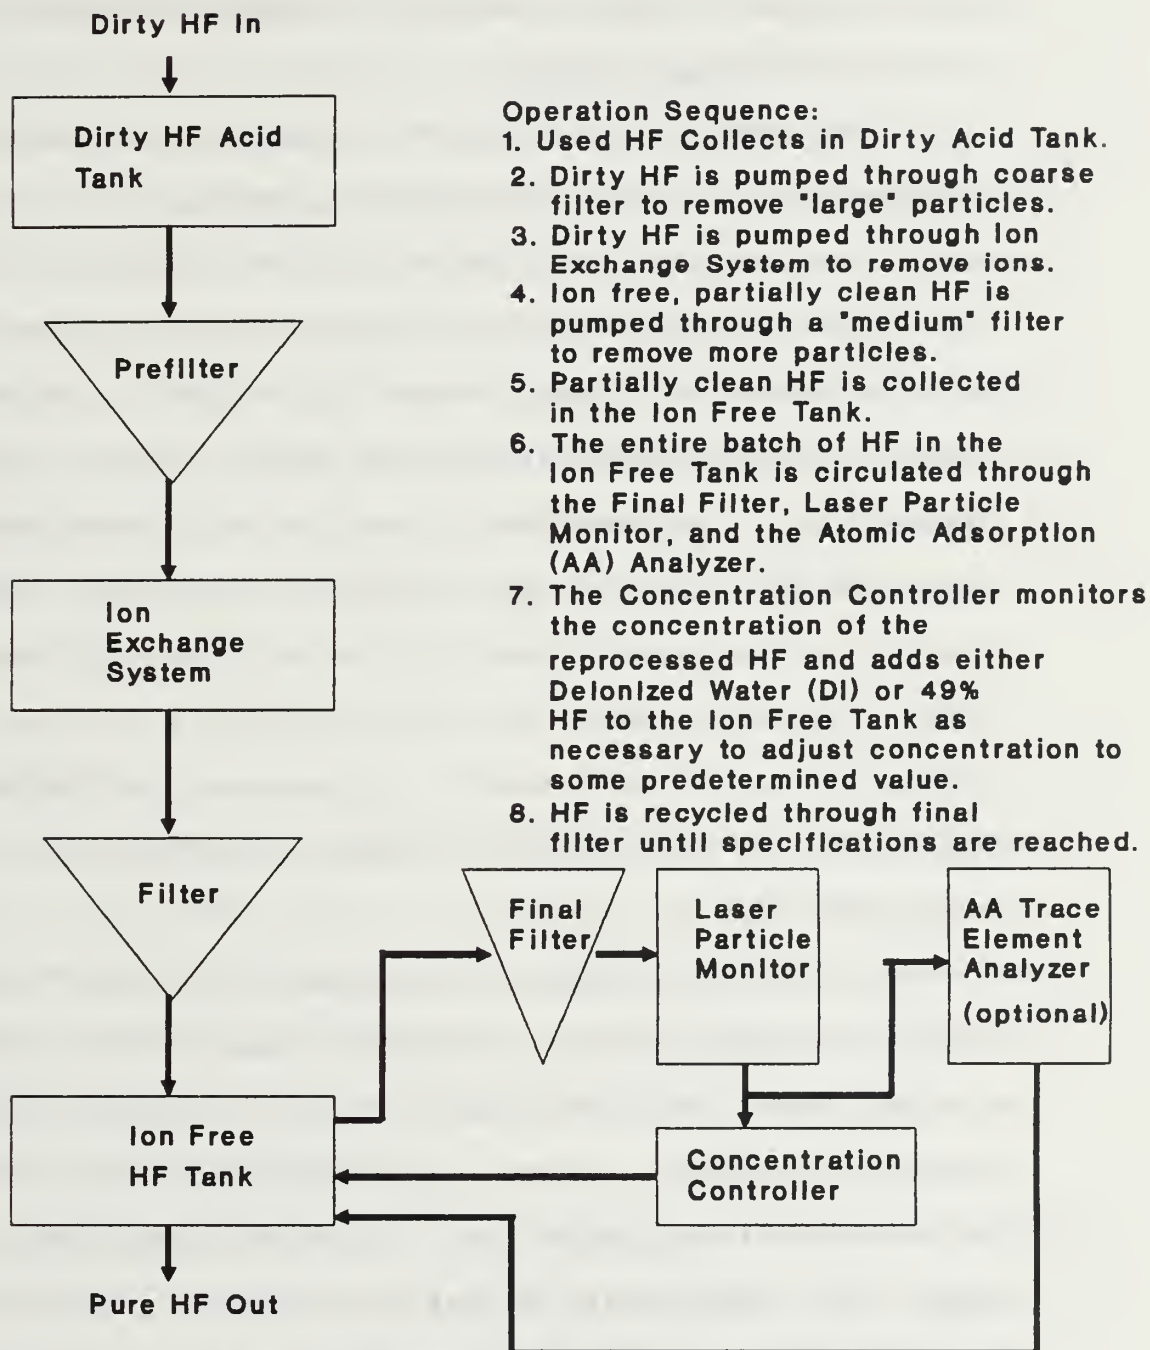

ampules and wafer etching operations that were described in Chapter 2. The reprocessor removes ionic and particulate impurities via ion exchange and filtration and claims to reduce chemical acquisition costs by 96% and hazardous waste disposal costs by 90% [4]. Figure 9 is a schematic diagram of the technologies incorporated by the reprocessor.

Hydrofluoric acid exhibits highly toxic and corrosive properties and therefore its disposal is strictly regulated. HF is used to remove silicon dioxide from the wafers and to clean the quartzware used to hold wafers in diffusion furnaces and reaction chambers. HF waste streams are composed of both concentrated cleaning and etching solutions and rinsewaters. Typical semiconductor HF waste streams contain a fluoride concentration of 3 to 5% and have a pH of less than 2 [4].

HF solutions of 10-20 weight percent, with distilled deionized water, are commonly used to clean the quartz tubes, and 0.5-10 weight percent to etch oxides. The purity of the HF solution directly impacts product yield and reliability, because the more pure the solution is, the better cleaning properties the HF exhibits. Particulate impurities in the HF solution tend to adhere to the wafers and produce defects that cause product failures. For this reason, the tendency is to use ultrapure HF and then discard it after one use. The Athens Corporation reprocessor extends the useful life of the HF solution thus reducing waste.

The HF reprocessor is designed to operate in line with a

Figure 9 Schematic Diagram of HF Reprocessor

REFERENCE: Davison et. al. "The Use of Reprocessed HF In Semiconductor Quartz and Wafer Cleaning Operations," The Electrochemical Society, 90 (9), 1989.

quartz tube cleaner and treats fifty gallon batches of HF waste solution. Spent HF is collected in the used acid tank and is pumped through a series of progressively finer filters and an ion exchange system.

A key component of the HF reprocessor is the ion exchange system. Ion exchange works because HF is a weak acid so relatively few H and F ions are present to compete with other cationic and anionic impurities for the active sites on the ion exchange resins [4]. Typical cationic impurities encountered are metals such as Silver (Ag), Aluminum (Al), Calcium (Ca), Chromium (Cr), Potassium (K), Magnesium (Mg), Sodium (Na), Lead (Pb), and Zinc (Zn). Typical anionic impurities include Chloride (Cl) and Bromide (Br). The resins also have little affinity for small, monovalent ions like H and F. Accumulated particulate impurities are periodically removed by replacing the filter cartridges.

On a series of tests, the authors collected "before" and "after" samples of reprocessed HF to measure the impurities at each point. The reprocessor showed a marked reduction in impurities (metals, anions, silicon dioxide, etc.) from the parts per million range (ppm) to the parts per billion (ppb) range. The reprocessed HF was then used in a semiconductor manufacturing process and compared with the reliability of a control HF solution. The control was ultra-pure semiconductor (ULSI) grade HF normally used in the manufacturing process.

The two methods used to evaluate the results were the "Full Chip Gate Oxide Integrity" (FCGOI) test and the Capacitance-Voltage (CV) characteristics test. These two tests are typically used in manufacturing process as a quality control check to ensure that the semiconductors exhibit the required electrical properties. The authors [4] found that there were no significant differences between any of the reprocessed HF test groups and the control HF solution. They concluded that the HF reprocessor produced sufficient quality HF for cleaning quartz tubes. They also stated that the data looked promising for wafer cleaning but further studies were needed prior to full production integration.

Case Study 2

The second Case Study involved the recycling of N-Methyl Pyrrolidone (NMP) which is a commonly used solvent in the wafer manufacturing process [1]. The operation is designed to separate NMP from polyamide, a passivator that builds-up between layers on the wafer, and deionized water which is used as a rinsing agent.

The recycling facility operated in a 10,000 gallon batch mode with an operation time of 2 to 3 weeks. Figure 10 is a schematic of the applicable technologies. Two major processes are involved: (1) evaporation of the water in a single staged packed column followed by (2) flash distillation of the NMP from the polyamide. The condensed

water is discharged into an onsite activated sludge wastewater treatment unit for biodegradation of any residual polyamide or NMP. The recovered polyamide stream is sold to a reclaiming company for further separation. The recycled NMP stream from the distillation column is analyzed for purity, turbidity, and chloride content. Specifications for the recycled NMP require 99.5% purity, less than 0.5 ppm chloride, and non-detectable turbidity. NMP that does not meet these requirements is processed again by the distillation unit and purified NMP is reused onsite. The dimensions and temperature ranges used are given on Figure 9. The estimated capital cost of the NMP recycling facility was \$630,000 (1986 dollars) for both design and construction. Annual operation and maintenance costs were approximately \$21,000. The authors assumed a ten year operating life and a ten percent effective annual interest to obtain a net present worth in 1986 of \$760,000.

The cost for virgin NMP was approximately \$10 per gallon (1986 dollars), and the estimated cost for reclamation of the NMP was approximately \$6 per gallon (\$4 net savings). For this particular manufacturing facility, the estimated payback period of the recycling unit was 18 months.

CHAPTER 7 SOURCE REDUCTION

The majority of the waste minimization effort ongoing in the semiconductor industry appears to be in the area of source reduction. As shown in Figure 4, Chapter 3, source reduction accounts for numerous techniques of waste minimization and is the preferred method over recycling by EPA [14]. Source reduction is any activity that reduces or eliminates the generation of hazardous waste at the source, usually within a process. Techniques of source reduction include optimization of processes, equipment, and the operations involved in generating the waste.

One area of Source Reduction that is proving effective in the semiconductor manufacturing process is the use of acid spray processors for cleaning and etching wafers instead of the standard batch processing in an acid bath. Acid spray processing can reduce chemical consumption by using the cleaning chemical in the "on demand" mode, whereas, in batch processing, once the chemicals are mixed, they have a specific lifetime after which the cleaning ability of the solution is substantially reduced [15]. The advantage of using cleaning chemicals only when they are needed, as in spray processors, is that it eliminates the need to replenish spent chemicals that result from batch processing.

Another substantial reduction of process chemicals can be accomplished through the use of gas and vapor phase processing, as compared to liquid phase processing in the wafer cleaning sequence. In a recent symposium, [15] eight

of the fifteen papers that dealt with new cleaning methods were related to gas phase processing. One of the advantages cleaning with chemicals in gas phase is that large volumes of wafers can be processed relatively quickly with smaller volumes of chemicals. For example, the Excalibur Anhydrous Hydrogen Fluoride cleaning tool, manufactured by FSI International, can clean 90,000 wafers using a five pound bottle of anhydrous HF gas [16]. This compares to a conservative estimate of 9,360 liters of 12:1 HF deionized water mixture to clean the same number of wafers.

The following case studies provide documented examples of source reduction used in the semiconductor industry.

Case Study 3

MEMC Electronic Materials Corporation manufactures silicon wafers for sale to semiconductor and other electronic component manufacturers. The company has developed a strategy for managing its hazardous waste by concentrating on waste elimination through changes in product design and manufacturing technology. The company won the 1990 South Carolina Governor's Pollution Prevention Award [17].

The MEMC plant in Spartanburg, South Carolina has completed a number of waste elimination projects, which included elimination and substitution of certain highly toxic chemicals. During a period when MEMC's manufacturing output increased by 10 percent, chromic acid use dropped by 96% due to manufacturing technology changes [19]. The reduction was accomplished by developing a new acid etchant formula

which does not employ chromium trioxide and generates no hazardous waste. The MEMC etch is a copper nitrate-based etchant.

Chromic acid based etching solutions have been used in the silicon wafer manufacturing industry for many years. The etchant yields hexavalent chromium waste which is hazardous, and for MEMC this was a cause for increasing costs due to disposal and treatment restrictions. In 1987, MEMC began a program to replace the chromic based etchant in its manufacturing process by developing an alternative etchant that could produce the same favorable performance characteristics as chromium without the regulatory side effects. Certain criteria were set for the new etchant that included: (1) the formula could not contain any harmful metallic species; (2) the etch rate and behavior had to be similar to chromic based etch; (3) the etchant had to have a long lifetime; (4) a low level of solution heating was desirable; (5) the solution could not generate any unusual or dangerous gases; (6) the etchant could not produce sludge or solid waste; (7) defects must be clearly defined on the wafer surfaces; and (8) the formula must be easily adapted to existing facilities [19].

Based on these criteria, MEMC tested a number of etch solutions and found that a copper nitrate based etchant proved the most promising. It met all criteria to some degree and, most important to MEMC, was the absence of a hazardous metal. In addition, the MEMC Copper Nitrate etch

has a long lifetime, no sludge buildup with repeated use, no unusual gases generated, and is slow to heat under normal usage.

As a result, the copper based etchant was substituted for chromium-based etchants on all but one silicon product. The chromium treatment sludge at the facility was reduced drastically. Between 1988 and 1991, the plant eliminated 53,800 pounds per year of chromium sludge, an overall reduction of 81 percent. In addition, the chromium content of the sludge was reduced from 47,000 ppm by weight to 6,200 ppm. MEMC also instituted a number of other waste minimization activities which saved the plant more than \$380,000 annually during this time period [17].

Case Study 4

This Case Study involved the use of an Automated Photoresist Dispense System [1]. Photoresist is one of the most expensive chemicals used in the semiconductor manufacturing process. Typical costs range from \$200 to \$400 per gallon. Photoresist waste is not one of the larger waste streams, but the cost of the chemicals motivated this facility to install an automated dispensing system.

Prior to automation, the one gallon bottles storing the photoresist chemicals were visually monitored and replaced by the operators. Typically, operators replaced used bottles containing approximately 2 inches of photoresist in the bottom to prevent the system from running dry. Eventually

the waste from each bottle was mixed and disposed of offsite. The time and labor required for monitoring, high cost of new chemical, and disposal costs involved with the waste made the system uneconomical.

The automated system was designed and sold by Tritec Industries, Mountain View, California and now provides maximum usage of photoresist from the supply bottles and continuous operation with minimal operator assistance. The automated system reduced photoresist waste for this manufacturer by fifty percent. A schematic representation of the dispense system is presented in Figure 11.

Basically the system connects two photo resist bottles to a photoresist reservoir for continuous supply. An alarm sounds when either bottle is empty notifying the operator to replace it. Pneumatically controlled pumps feed the photoresist from the reservoir through a filter to the dispensing point. Air is vented from the pump through an automatic valve to prevent air bubbles from being dispensed on the wafer surface.

Eight of the automatic dispense systems were installed in November 1985 at a cost of \$30,000, or about \$3,750 each. The financial justification of purchasing the system only focused on the wastage left in the bottles. A one gallon bottle with a residual of 1.5 inches in the bottom amounted to a wastage rate of approximately 18% by volume. With an average weekly usage of 22 gallons at a purchase cost of \$260 per gallon in 1985, the potential cost savings associated

Figure 11 - Automated Photoresist Dispensing System

NOTES:

1. Photoresist is fed from Bottle A until empty at which time an alarm sounds and material begins feeding from Bottle B.
2. Reservoir capacity of 150 cc with level sensor.
3. An automatic air vent off the pump prevents trapped air from being fed to dispensing nozzle.

with not wasting any photoresist amounted to \$54,000 per year. The payback for the company was less than one year.

Chlorofluorocarbon (CFC) Reduction

In January 1992, legislation was signed by the President of the United States that called for the complete elimination of chemicals that deplete the ozone layer in the atmosphere by 1995. The majority of these chemicals are Chlorofluorocarbons (CFCs). Figure 7, Chapter 5, shows that between 1987 and 1990, the California semiconductor industry released 823,444 pounds of Freon 113 (Trichlorotrifluoroethane) which was approximately 23% of the total chemicals released to the atmosphere. Freon 113 is one of the CFC chemicals that will be phased out in the future.

The Clean Air Act specifically states that by December 31, 1999, EPA must promulgate a production phase-out schedule for class II ozone depleting chemicals (Table 3). On the next day, January 1, 2000, the production and consumption of class I ozone depleting chemicals is prohibited. Recent scientific evidence suggests that this timetable is not soon enough [20].

The electronic industry as a whole is a moderate user of CFCs which are used as cleaning or degreasing agents in the manufacturing process. Alternative chemicals and cleaning systems have been proposed or implemented that will reduce the use of CFCs.

The following case study provided options to reduce

CFC consumption and solvent usage in general.

Case Study 5

The Hewlett Packard Corporation in conjunction with the State of California, Department of Health Services, completed a study in 1988 on the reduction of solvent wastes at their San Jose, California manufacturing facility [11]. They concluded that solvent segregation, solvent substitution, direct solvent reuse, distillation and evaporation could be utilized to accomplish a 70% solvent reduction.

Segregation of chlorinated solvents from non-chlorinated solvents was recommended to facilitate waste reduction by increasing recyclability. In fact, a telephone survey of commercial recycling facilities on ways that generators can improve the recyclability of solvent wastes found that minimizing water mixing, separating chlorinated from non-chlorinated solvent wastes, separating aliphatic from aromatic solvent wastes, and separating freons from methylene chloride were the best "housekeeping" avenues to recycling.

Solvent substitution is becoming the only alternative for CFC consumption. One approach is the use of water-alcohol cleaning systems utilized by the printed circuit board industry [8]. The aqueous cleaners can result in significant cost savings in the waste treatment and disposal requirements, but the cost per gallon coupled with cleaning efficiency of the two alternatives are roughly equivalent for the semiconductor industry [11].

Certain disadvantages of aqueous cleaners unique to the

semiconductor industry include: (1) possible inability of aqueous cleaners to provide the degree of cleaning required; (2) incompatibility between the material of construction and the cleaning solution; (3) need to modify or replace existing equipment; and (4) presence of moisture on parts leaving the cleaning operation which would require air or heat drying.

In all, the use of non-CFC chemicals in the semiconductor industry appears to require more research to ensure that the required level of cleaning along with compliance with current and future regulations is maintained. In an industry where tight production schedules and stringent quality control requirements are adhered to, there is a tendency not to try new products for fear of tampering with success. But as far as CFCs are concerned, the regulations are going to prohibit their use in the near future so that other alternatives will have to be found.

CHAPTER 8 CONCLUSIONS

1. The semiconductor industry is represented in 29 states generating over 7000 tons of hazardous waste with California, Pennsylvania, Texas, Missouri, Massachusetts, and Indiana accounting for over 50 percent of the waste. Nearly 90 percent of these hazardous wastes are spent solvents, acids, and bases. The largest waste stream generated by the semiconductor manufacturing processes is a neutralized acid-waste water stream that is currently exempt from the Resource Conservation and Recovery Act regulations but controlled by the NPDES permitting system under the Clean Water Act.

2. The semiconductor market is expected to expand by nearly 25 percent in next four years. Waste minimization will become increasingly important if not due to economic incentives then due to liability issues. Various states are realizing this and beginning to pass waste minimization regulations that will directly affect semiconductor manufacturing operations.

3. No specific EPA document of sponsored research was found for the semiconductor industry as a whole. The majority of research is sponsored by the Semiconductor Industry Association, Cupertino, California or individual companies. Many times this research is considered confidential due to the competitive environment of semiconductor manufacturing. This is not conducive to technology transfer within the industry, and as such waste minimization practices within the semiconductor industry are

difficult to document. A reduction of hazardous waste has occurred over the past four years as shown in Tables 2, 3, and 5, but specific actions to achieve this reduction are for the most part not available through public documentation.

4. The environmental regulations are the driving force behind waste minimization within the semiconductor industry. The 1990 Clean Air Act Amendments will surely affect how ozone depleting and volatile organic chemicals used in the semiconductor manufacturing process are deposited into the atmosphere. California and Texas appear to be two states that are emphasizing waste minimization directly through legislation.

5. Source Reduction, as defined in Figure 4, Chapter 3, is the preferred avenue of waste minimization by EPA and appears to be the thrust of efforts currently underway by the semiconductor industry. This is a general trend found after researching numerous technical journals, trade publications, and consultation with professionals employed at manufacturing facilities and consulting firms. This is not a coincidence. Source reduction provides the most opportunity for waste minimization and is often the quickest avenue for reduction.

6. Substantial waste minimization normally requires expenditure of capital dollars and a firm commitment from company executives that control critical resources. Initially, resources should be directed toward "housekeeping" measures with an emphasis on a total waste audit of the semiconductor manufacturing plant. These two actions allow

those most familiar with a particular manufacturing process to "step back" and take an objective look at production practices and how waste is disposed. The waste audit is also important in later stages of a waste minimization program by categorizing waste streams to provide the most reduction for scarce resources. Reference 14 provides a good overview of the waste audit process. A team approach consisting of both labor and management representatives appears to work best.

7. Overall, the incentives outweigh the disincentives for waste minimization in the semiconductor industry.

CLASS II :			

APPENDIX D

Appendix D is the supporting data for Figures 6, 7, and 8. The data includes the major chemicals released by the California Semiconductor Industry for years 1987 through 1990 to the Air, POTW, and Off-Site respectively.

D

APPENDIX D

Figure 6 Chemicals:

1,1,1-Trichloroethane
1,1,2-Trichloroethane
1,1,4-Trichlorobenzene
1,2-Dichlorobenzene
2-Ethoxyethanol
Acetone
Ammonia
Ammonium Sulfate (soln)
Chlorine
Dichloromethane
Ethylene Glycol
Freon 113
Glycol Ethers
Hydrochloric Acid
Hydrogen Fluoride
Isopropyl Alcohol
Lindane
Methanol
Methyl Ethyl Ketone
Nitric Acid
Phenol
Phosphoric Acid
Sulfuric Acid
Tetrachloroethylene
Trichloroethylene
o-Xylene
p-Xylene

Figure 7 Chemicals:

1,1,1-Trichloroethane
1,1,2-Trichloroethane
1,2,4-Trichlorobenzene
2-Ethoxyethanol
Acetone
Ammonia
Ammonia Nitrate (soln)
Ammonia Sulfate (soln)
Copper
Copper Compound
Cyanide Compound
Ethylene Glycol
Freon 113
Glycol Ethers
Hydrochloric Acid
Hydroquinone
Isopropyl Alcohol
Lead Compound
Methanol
Nickel Compound
Nitric Acid
Phenol
Phosphoric Acid
Sulfuric Acid
o-Xylene
p-Xylene
Zinc Compound

Figure 8 Chemicals:

1,1,1-Trichloroethane
1,1,2-Trichloroethane
1,2,4-Trichloroethane
1,2-Dichlorobenzene
2-Ethoxyethanol
Acetone
Ammonium Sulfate (soln)
Copper Compound
Dichloromethane
Ethylene Glycol
Freon 113
Glycol Ethers
Hydrochloric Acid
Hydrogen Fluoride
Isopropyl Alcohol
Lead
Lead Compound
Methanol
Methyl Ethyl Ketone
Nickel Compound
Nitric Acid
Phenol
Phosphoric Acid
Sulfuric Acid
Tetrachloroethylene
Toluene
Xylene (mixed isomers)
Zinc compound
